Methods for Brooding Chicks

radiant panels, infrared lamps compared for electricity used, weight gains, feed needs, mortality, feathering

Wilbor O. Wilson and Leroy C. Kleist

Two widely used brooding methods—radiant heat panels and infrared lamps—were tested in the winter and fall of 1951 on the University of California Poultry Farm at Davis.

The chicks for each test were kept in two adjacent pens 10' x 14' separated by wire partitions. Wood shavings were used for litter. Cardboard draft shields 12" high were used in all pens for the first week. Both tests lasted for six weeks.

The winter test began January 26, 1951 and the fall test began September 12. The control brooder was started at 95° F; the temperature was dropped 5° each week. All chicks were fed the same ration. White Leghorns and New Hampshires were used in the winter tests, and New Hampshires were used in the fall experiments.

Winter Test

The brooder in the control pen was an electric fan-ventilated unit with an insulated hover 56" in diameter. The heating element was 550 watts. A wafer thermostat and microswitch controlled the temperature under the brooder.

The radiant heat panel was constructed of tempered glass plate which had been fitted with a grid made of aluminum alloy. This served as a 1,000-watt heating element. The panel was 18" x 24". A cartridge type of an on-off thermostat controlled the heat.

Infrared heat lamps were placed on a frame. The lamps were tilted outward at a 30 degree angle from vertical. Four 250-watt lamps were used. One lamp was connected to an on-off type of thermostat.

Fall Test

The control brooder was the same as was used in the winter test. Four 125 infrared heat lamps on a frame were controlled with a manually operated voltage regulator.

A radiant heat panel brooder was made to utilize low temperature heating elements covering an area 4' x 6'. The brooder was hinged at the rear to one wall at a height of 10". The front was raised and lowered by means of rope and pulleys.

Records were made of kilowatt hours—KWH—consumed, body weight gains, feed consumption, mortality, feathering,

The effect of picking on a conveyor is evaluated as resulting in an average savings in time of 32.7% and an average increase in production of 49.4% or a reduction in manpower of 49.4%. Since the conveying method will require additional manpower for operating equipment and loading fruit, the picking time of the tests is increased by 25% for this contingency. Since the operation would now compare with picking and stacking on a highway truck, 10% has been added to time for existing method to provide for this. Comparisons now indicate a savings in time of 23.6% and an increase in production of 31.4% or a reduction in manpower of 31.4%. All results include time spent on carrying conveyor down the rows as needed and as such are a more conservative estimate of the values of the conveyor studied.

The results of the preliminary tests of the conveyor indicate that eliminating materials-handling from harvesting will yield the results estimated. Materials-handling required 20% of harvesting process so eliminating it would produce a savings in time of 23% and an increase in production of 31%.

Tests for Conveyor Type

Two possible types of conveyors might be used in harvesting, the in-row type and a cross-row type.

A cross-row type could be mounted across the rows and travel down the rows at a predetermined rate of speed. The pickers could be stationed in each row between plants and pick plants on both sides, following the conveyor down the row.

Tests were performed to provide indications as to feasibility of the use of a cross-row conveyor. These tests involved:
1. The movement of equipment over plants and down the rows between plants.
2. Picking plants using a 2-man crew, one picker on each side of the plant.
3. The use of fork-lift equipment to move pallets of lugs from trailer to truck.

In the first test a high tractor was used to drive down the rows between plants. Planting was Pearson tomato on a 6' row by 3' spacing. The tractor wheel span was opened to 6' for the test. Additionally a short wheel-base truck having a 6' wheel span was also driven down the rows between plants. Estimates of the damage to plants and fruit were then made. These turned out to be comparable to and smaller than most damage found after a group of pickers has been in a field.

In the test of a 2-man crew for picking, each man picked one side of a plant and placed the fruit into a common lug located next to the plant. A reduction in time of 6% was obtained. The same results should hold when picking on a conveyor and moving along behind it.

Fork-lift equipment was tested but the results were inconclusive because only very heavy equipment was available and while the job of transferring pallets was accomplished it was very time consuming.

Immediate Steps

Steps to improve productivity of harvesting practices which can be taken by all growers immediately are:
1. Use 2-man crews for picking, one picker on each side of plant-row. 2. Pick directly into lugs and have lugs carried out after one or two are filled rather than all at once. 3. Give more training to low-producing pickers to bring up their skills. 4. Carry out some selection of pickers. It is not merely a matter of using low producers but actually a matter of increasing yield by reducing waste due to trampling of plants and fruit. 5. Take steps to improve working conditions, such as providing a supply of cold water at work areas and salt tablets in containers at each water barrel; requiring the use of rest periods in mid-morning and mid-afternoon; and experimenting with moving the working time during the day so that harvesting starts at a very early hour and is completed in the early afternoon to reduce the effects of heat.

Conveyors Compared

Experience during the 1951 survey indicated that the in-row type of conveyor may not be as satisfactory as the cross-row type. There may be losses in picking time associated with moving the conveyor from one row to the next. These losses can result in reducing the savings as evaluated in the survey.

Estimates of the value of the use of conveyors in harvesting based on tests during the survey are 15% to 25% savings in time and 25% to 30% reduction in labor or increase in production. The survey reported here, should be considered as preliminary. Many questions having a bearing on the efficiency of harvesting operations are still unanswered. Some of them need further study—planning and developing conveyors, handlaking, new plant types, mechanical picking, field layout, preparation and irrigation, work efficiency in regard to rest periods, working time and period, fatigue studies and cost studies.

Wilbur O. Wilson is Assistant Professor of Poultry Husbandry, University of California College of Agriculture, Davis.

Leroy C. Kleist, Junior Specialist of Agricultural Engineering, University of California College of Agriculture, resigned October 1, 1951.
