Quick Decline Studies

rootstock investigations test various top-root combinations in search of tolerant citrus varieties

W. P. Bitters and E. R. Parker

The second of two articles on quick decline as influenced by top-root relationships

Two sets of rootstock experiments were set up to determine the tolerance of certain top-root combinations to quick decline.

In 1945 and 1946, 620 trees of various top-root combinations were planted as replants in the quick decline area of the Azusa-Covina district. Ten rootstocks were included. All trees were exposed to natural infection by the quick decline virus, and the trees in one orchard were also inoculated with buds from diseased trees.

In 1948, 2,112 trees of Valencia oranges on 125 different rootstocks—1945 seed—were planted at Baldwin Park. Half of the trees were inoculated with buds from diseased trees.

In the 1945-46 plantings trees generally grew slowly, probably because they were frequently planted in orchards which were due for removal and had poor care. Symptom expression was initially less pronounced than on the trees at the Baldwin Park planting. At Baldwin Park the inoculated trees on some rootstocks were much more readily affected by inoculation with quick decline virus than others. By August, 1950, 41.6% of the inoculated trees at Baldwin Park were affected while 10.1% of the check trees were infected by the vector. Trees on some of the roots—such as sour orange or shaddock—appeared to be more seriously affected by natural infection than those on roots of the mandarin hybrids, trifoliate orange hybrids, and others.

Most of the inoculated trees made less growth than the check trees, in many cases the only observed effect of inoculation. Growth was reduced in trees on the roots of sweet orange, some of the mandarin, and trifoliate hybrids; but not on some of the lime stocks, Rough lemon, and a few other roots.

The conclusions as to the tolerance to quick decline of Valencia trees on the various stock combinations are in many cases tentative.

The results are principally based upon inoculation trials made in test plots and may not be typical of results obtained under conditions of natural infection.

Sour and Sweet Oranges

Twenty varieties of sour orange were used as rootstocks for Valencia oranges.

Some trees in each of these combinations developed quick decline symptoms. In both plantings the bittersweet group of sour orange appears to be more susceptible than the standard sour group. Two years after inoculation 70.7% of the inoculated trees at Baldwin Park showed symptoms, compared to 20.7% of the checks. The possibility of finding a variety of sour orange tolerant to quick decline seems highly improbable.

The growth of trees on 12 of the 14 varieties of sweet orange stocks was reduced on the inoculated trees at Baldwin Park. In general the check trees and the trees in the 1945-46 plantings appeared healthy. Only a few of the inoculated trees—except a selection of the Bessie variety—developed mild symptoms similar to those of quick decline. However, the condition of some of the inoculated trees on sweet root has not improved, and the stunting effect is accompanied by small leaves and partial defoliation.

Shaddocks and Hybrids

The shaddocks used as stocks for Valencia orange are very susceptible to quick decline. The nine shaddocks tested appear to be equally susceptible and show symptoms about as rapidly and to the same degree as trees on sour orange roots. Symptom development was slower in the 1945-46 plantings.

Trees on the shaddock x sweet orange hybrid stocks developed symptoms earlier and to a more severe degree than those on the sour orange stocks. Growth of the inoculated trees as compared to the uninoculated trees was reduced more than in any other group of combinations. The fact that shaddock was one of the parents of the hybrid did not make the hybrid less susceptible.

Grapefruit and Limes

Many of the inoculated orange trees on grapefruit stock at Baldwin Park show symptoms of quick decline and reduction in growth. These effects are sufficiently severe to classify these stocks as susceptible, although symptoms are milder and slower to appear than on sour orange stocks. In the 1945-46 plantings sweet
orange trees on grapefruit roots occasionally showed mild symptoms. Valencias budded on acid or mandarin-type lime stocks appear to be tolerant to quick decline two years after inoculation. Trees on the Palestine sweet lime and a lime-orange hybrid appear to be susceptible.

Lemon and Hybrids

Among the lemons, lemon hybrids, and several lemon-like selections only three out of 14 varieties appear to be tolerant when used as stocks for Valencias. These are two common varieties of Rough lemon and a Rough lemon type from India. Symptoms are very pronounced on some of the lemon—Eureka and Lisbon—and lemon-like roots. Trees on two selections of Khoubz-el-Arsa and the Rabat—possibly a hybrid of lemon x sour orange—appear to be even more susceptible than trees on sour orange stock.

Mandarins and Hybrids

Valencias on the mandarin stocks are slightly stunted by the inoculations. The degree of stunting is comparable to that on sweet stock and is accompanied by small leaves and thin foliage. The Kinkuni and Willow Leaf varieties are the most severely stunted and the Cleopatra mandarin the least. The uninoculated check trees of these varieties and uninoculated trees on King mandarin in the 1945-46 plantings are healthy.

Some mandarin hybrids appear to be tolerant, others susceptible, as stocks. Symptoms are milder, and slower to appear than in trees on sour orange roots. Trees on nearly all 20 mandarin-hybrid varieties are stunted. The inoculated trees on San Jacinto tangelo and two tangors—hybrids of Willow Leaf x Valencia and Willow Leaf x Blood orange—are not appreciably reduced in growth and have developed no symptoms. The trees on Kara show no symptoms other than moderate stunting. Two selections of Thornton tangelo, a tanger—hybrid of Owari satsuma x Valencia—Owari tangelo, Minneola tangelo, Sexton tangelo, and Sampson tangelo appear to be susceptible. The trees on Sampson tangelo root in the 1945-46 plantings displayed only a lack of vigor. It may be that all oranges budded on tangelo are susceptible combinations and that the trees on the San Jacinto have escaped infestation or have not as yet developed symptoms.

Trifoliate Orange Hybrids

Mild symptoms resembling quick decline are present on a few trees on roots of most varieties of trifoliate orange. The inoculated trees on most trifoliate stocks are stunted, but some difference between varieties is apparent. A tetraploid strain appears least satisfactory, the Rubidoux and Pomeroy strains most promising in tolerance. The appearance of the inoculated trees has improved after the first onset of symptoms.

Among the hybrids a citremon appears most susceptible. A few trees on each of these roots show varying degrees of stunting accompanied by small leaves and thin foliage. The condition of such trees tends to improve. None of the check trees are affected. Trees on the Morton citrange and Troyer citrange in the 1945 planting are healthy and vigorous, showing no indications of decline.

Miscellaneous Stocks

Some of the inoculated trees in this group on the Ichang pummelo and Ichang lemon have developed more severe symptoms and display the greater stunting. Trees on the Yuzu and Kansu are least affected, and their appearance is generally improving.

Trees on Citrus moi still appear toler-

ant. Those on Citrus macroptera and on the Bigaraldin are susceptible.

Observations are being continued and plantings of trees on additional roots added. The grower is advised not to plant trees unless their susceptibility to quick decline has been determined; and to buy trees from a reliable nurseryman who can provide a past history of the top-root combination.

W. P. Bitters is Assistant Horticulturist, University of California College of Agriculture, Riverside.

DONATIONS FOR AGRICULTURAL RESEARCH

Gifts to the University of California for research by the College of Agriculture accepted in February, 1952

BERKELEY

Heckathorn and Co. 10 lbs. 50% wettable chlordane For experimental purposes on garden cemestidpe
Loring Hoag 5 lbs. rose clover For establishing range pasture test plots
H. D. Hudson Mfg. Co. 5 lbs. Smilie Admiral Duster No. 766
Julius Hyman Co. 50 lbs. P 162 25 lbs. emulsifier
For experimental work on control of poultry mites
For nutritional research
Naugatuck Chemical 10 amoles leucovorin $233.35
Lederle Laboratories Division of American Cyanamid Co. For embryonic research
For use in fumigation studies of crown gall bacteria in soils and control of Armillaria and Dematophora root rots
For experiment on control of poultry mites
Mercel & Co., Inc. 20 mg. crystalline vitamin B12 For nutritional research
For use in fumigation studies of crown gall bacteria in soils and control of Armillaria and Dematophora root rots
Naugatuck Chemical 50 mg. aminopterin $59.08
For experimental purposes
Turkey hatchng eggs
Lederle Laboratories Division of American Cyanamid Co. $959.08
For experimental purposes
For continuation of work on production of seed and quality of forage
Cannons League of California $3,125.00
For experimental purposes
In continuation of work on crown gall in soils and control of Armillaria and Dematophora root rots
California Turkey Growers Association
Turf management
Ed Heitman 1 registered Duroc gilt
For use in the breeding herd
Jackson & Perkins Co. 153 registered Duroc gilt
For experimental purposes
Lederle Laboratories Division of American Cyanamid Co. and license to grow same for cut flowers
Against Staphylococcus aureus in HCL crystalline 50 grams
For embryonic research
Linke Air Products Co. For experimental purposes
For use in fumigation studies of crown gall bacteria in soils and control of Armillaria and Dematophora root rots
Lederle Laboratories Division of American Cyanamid Co.

DAVIS

American Potash Institute, Inc. 1 ton potassium sulfate For experimental purposes on garden cemestidpe
For continuation of work on orchard soil fertility
Dr. James A. Berry laboratory articles For the Division of Food Technology
For experimental purposes
Cal. Com. Rel. of Electricity to Agriculture: $3,125.00
For the Division of Food Technology
Continuation of support of investigations on use of electricity in agriculture
California Turkey Growers Association. $499.08
For embryonic research
Turkey hatchng eggs
Cannons League of California $3,125.00
For experimental purposes
In continuation of work on crown gall in soils and control of Armillaria and Dematophora root rots
California Turkey Growers Association
Turf management
